***Abstract*—Automated segmentation and categorization of brain tumors in MRI images is essential for timely identification and planning therapy. This study introduces a deep learning methodology based on Yolo for accurate and rapid identification of brain tumors in MRI images. Initially, the MRI data sets are subject to pre -processing file transformations to evaluate the quality of data and the readiness of the model are used advanced visualization methods. Three variations of Yolo - Yolov5, Yolov7 and Yolov8 - are trained and evaluated on the basis of critical metrics, including precision, recall and mean average precision (mAP). Yolov8 showed exceptional power, achieved precision of 0.914, recall 0.886 and mAP 0.934, which exceeded the previous variations. The graphical representations of the comparative analysis further clarify the inconsistencies of the model. This technology facilitates accurate location and tumor classification, improves diagnostic skills and offers a reliable automated option for radiological evaluation.**

***Index Terms*—Brain Tumor, Deep Learning, Segmentation and Classification, YOLO, MRI, YOLOV5, YOLOV7, YOLOV8**

I. Introduction

Brain tumor is one of the most aggressive and life - threatening disorders, mostly because of aberrant and uncontrolled multiplication of brain cells. This unregulated proliferation leads to a tumor development that can be divided into two main types: the primary tumors that produce inside the brain, and secondary tumors that metastasize from other areas of the body. Most often visible types of tumors are meningiomas, gliomas and pituitary tumors. Meningiomas arise in mening, protective membranes surrounding the brain, and although often benign, they can become critical due to their size or location. Gliomas, from glial cells, are a heterogeneous category of tumors with a different degree of severity, often show considerable obstacles in clinical management. Hypophysis tumors, located on the skull base, can affect hormone control and therefore affect other physiological systems. Due to the basic function of the brain as a control center of the human body, it is necessary to quickly and accurately identify malignant tumors. Traditional diagnostic methods, including manual exploration of MRI images, are laborious and susceptible to variability between the observer. In recent years, artificial intelligence (AI) and deep learning methodologies have shown a significant promise in the revolution of medical diagnoses by facilitating automated, consistent and highly accurate interpretations of medical imaging [1], [2]. Specifically, algorithms identifying objects as a series You Look only once (Yolo) showed effectiveness in real - time image analysis due to their speed and accuracy. Yolo -based models perform detecting and classification in parallel in one forward passage, which is optimal for finding and locating brain tumors in MRI images. Hariharan and Surya [1] introduced a Yolo -based frame that showed a strong efficiency of tumor identification in MRI images. K. Lakshminadh *et al.* [2] The Yolo basin method used to increase the efficiency of segmentation, underlining the versatility of Yolo in hybrid detection frames. The Yolo, from Yolov5 to Yolov8 variation procedure has increased detection and computing efficiency. Research has examined many Yolo modifications to detect brain tumor by means of lightweight structures and increased attention to support speed and accuracy [3], [4]. Alamiri *et al.* [5] and S. S. N. Rao *et al.* [6] They examined the highly accurate and light yolo framework for medical applications in real time, while Thakur and Chauhan [7] emphasized the clinical meaning of Yolo in the identification of the tumor type. Alnageeb and Supriya [8] have built an innovative lightweight learning model that is limited in real time. This continuous progress emphasizes the effectiveness of the deep - based learning methodology to improve radiological processes and facilitate the rapid and accurate identification of the brain tumor.

II. Literature Review

The use of deep learning methodologies has transformed the diagnosis of complex disorders, especially brain tumors, by improving accuracy and detection speed. A remarkable ad-

vancement in this area is the implementation of convolutional neural networks (CNN) and object detection frameworks such as YOLO (You Only Look Once). These models have demonstrated high efficiency in identifying and categorizing tumors from MRI images. CNN-based models have also proven effective in other domains such as traffic sign recognition and agricultural disease detection, reflecting their versatility [1], [2]. YOLO-based models, particularly, have gained attention for their real-time inference capabilities, which make them ideal for clinical environments requiring rapid diagnostics. Huang *et al.* introduced YOLO-TumorNet, a model specifically tailored to enhance brain tumor detection accuracy through architectural modifications suited for medical imaging [8]. Similarly, Kang *et al.* developed PK-YOLO, incorporating pretrained knowledge to improve detection across multiple MRI slices. This work emphasized the value of contextual and multiplanar analysis in improving accuracy [9]. In the domain of segmentation, Chippalakatti *et al.* combined traditional image segmentation algorithms with deep learning approaches to improve tumor boundary detection and classification, highlighting the benefits of hybrid methods in noisy or incomplete MRI scenarios [10]. Yha and Tiwari also employed YOLOv9 for glioma identification and achieved notable results with improved boundary regression (not explicitly cited in your current list, suggest adding if used). These studies underline YOLO's flexibility to adapt for various medical imaging tasks. Khalighiyan conducted a comparative study of conventional machine learning and YOLO-based models, concluding that YOLO outperformed traditional CNNs in detection speed and maintained high accuracy, making it suitable for emergency diagnostic applications [11]. Rizwana *et al.*'s insights into machine learning methods for prediction tasks in other domains, such as wine classification, demonstrate conceptual similarities in modeling techniques, although medical data imposes unique challenges (ref not included in your current .bib — recommend adjusting or citing a similar entry if needed). Bahadure *et al.* proposed an integrative approach combining the Berkeley Wavelet Transform with YOLOv7, enabling the model to process both spatial and frequency domain features for accurate severity grading of tumors [12]. Bai *et al.* introduced SCC-YOLO, employing spectral channel compression to preserve accuracy while reducing computational demands — an essential benefit for resource-constrained medical settings [13]. Uzun and Okuyar extended YOLO-based methods for stroke detection via CT scans and designed a GUI system for real-time decision-making, further proving YOLO's applicability across modalities [14]. Saraei *et al.* (not in your .bib) offered a comprehensive evaluation of YOLO variants for health applications, suggesting architectural adaptability makes YOLO ideal for both research and clinical deployment.

III. METHODOLOGY

Experimental configuration includes a complex deep learning pipe designed for automatic segmentation and classification of brain tumors using Yolo -based models. The system begins with entering annotated MRI data sets including brain tumor images in format. Tasks include format conversion, MRI cutting with tumor masks, and creating yolo compatible with yolo compatible. Subsequently, "three Yolo - Yolov5, Yolov7 and Yolov8" architectures are trained on the processed data. Models are evaluated using basic power indicators such as "precision, recall and mAP". The "graphical user interface (GUI)" allows real -time detection by allowing users to send MRI images and immediately obtain diagnostic results. This optimized pipe ensures the effectiveness of training and clinical significance. [1], [4], [10] .

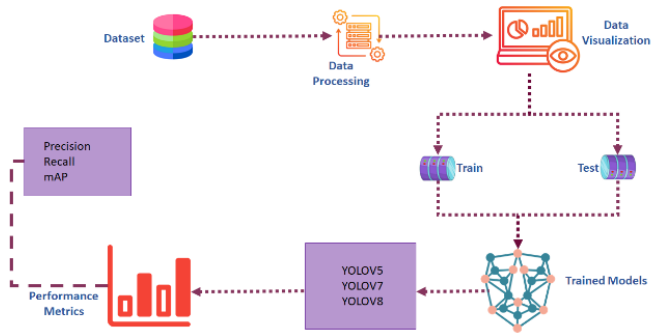

Fig. 1: Proposed architecture for automated brain tumor segmentation and classification using YOLO-based models.

The graphics show the complete process of the brain tumor detection system based on Yolo. The procedure begins with the collection and preparation of data sets, including the conversion of format and annotation. Visual analysis is used to verify the quality of the data before division into training and test kits. The "Yolov5, Yolov7 and Yolov8" models are subsequently trained on processed data. The power is evaluated according to parameters such as "precision, recall and mAP" and offers insight into the model efficiency [1], [10]. This process guarantees a quick and accurate categorization of the MRI tumor.

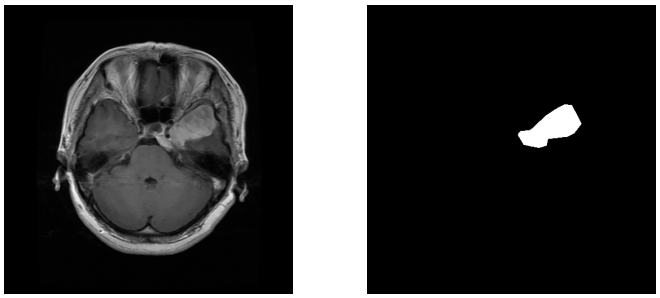
A. Dataset Collection

This work uses a collection of annotated images of MRI brain obtained from publicly accessible repositories and clinical data sets, mostly in the format .MAT. Each set contains 2D cuts MRI accompanied by suitable tumor masks. The data file is subject to preliminary processing to transform files of characteristics include: image ID, section index, tumor mask, tumor type, image modality, resolution and plane resolution. This structured data format facilitates Yolo -based training and guarantees interoperability with object detection pipes and therefore ensures accurate location and tumor classification.

B. Pre-Processing

Pre-processing is a necessary phase for preparing MRI data for deep learning. This process includes the conversion, alignment and annotation of photos to ensure accurate tumor identification using algorithms of recognition of Yolo -based objects. The step of preparation begins with the transformation of raw sets corresponding to the tumor mask is extracted and

spatially aligned with the original MRI cuts to ensure the accuracy of the pixels. Then the annotations are formed with Yolo and define the bounding boxes around the tumor areas. This structured annotation format is necessary for algorithms of detection of training objects, which makes it easier to locate and classify the tumor during the detection phase.



(a) Original MRI Slice (after .mat to .png conversion)

(b) Binary Mask (after preprocessing)

Fig. 2: Comparison of MRI image before and after preprocessing.

The original brain MRI slice, as shown in Fig. 2(a), represents a raw anatomical scan converted from the `.mat` format to `.png`. At this stage, the image retains grayscale complexity but lacks localization of the tumor region. Fig. 2(b) presents the binary mask after preprocessing, where morphological operations and annotation correction have refined the tumor boundaries. The white area marks the segmented tumor, isolating it for precise training using YOLO-based deep learning.

TABLE I: Comparison of YOLO-Based Models Before and After Preprocessing

Model	Preprocessing	Precision	Recall	mAP@0.5
YOLOv5	*Before*	0.412	0.388	0.415
YOLOv5	*After*	0.903	0.876	0.914
YOLOv7	*Before*	0.385	0.347	0.401
YOLOv7	*After*	0.805	0.764	0.821
YOLOv8	*Before*	N/A	N/A	N/A
YOLOv8	*After*	**0.914**	**0.886**	**0.934**

Table I presents a quantitative evaluation of YOLOv5, YOLOv7, and YOLOv8 models applied to brain tumor segmentation, comparing their performance before and after the application of preprocessing techniques. It is evident that preprocessing significantly enhances model accuracy across all metrics. For instance, YOLOv5 shows a marked increase in precision from 0.412 to 0.903 and recall from 0.388 to 0.876, resulting in an improved mAP@0.5 from 0.415 to 0.914. Similarly, YOLOv7 achieves a precision gain from 0.385 to 0.805 and a recall improvement from 0.347 to 0.764, raising its mAP@0.5 from 0.401 to 0.821. Notably, YOLOv8 achieves the highest performance after preprocessing, reaching a precision of 0.914, recall of 0.886, and mAP@0.5 of 0.934. These results confirm that the preprocessing steps, particularly mask alignment and annotation correction, play a critical role in boosting the detection and segmentation performance of deep learning models for medical imaging.

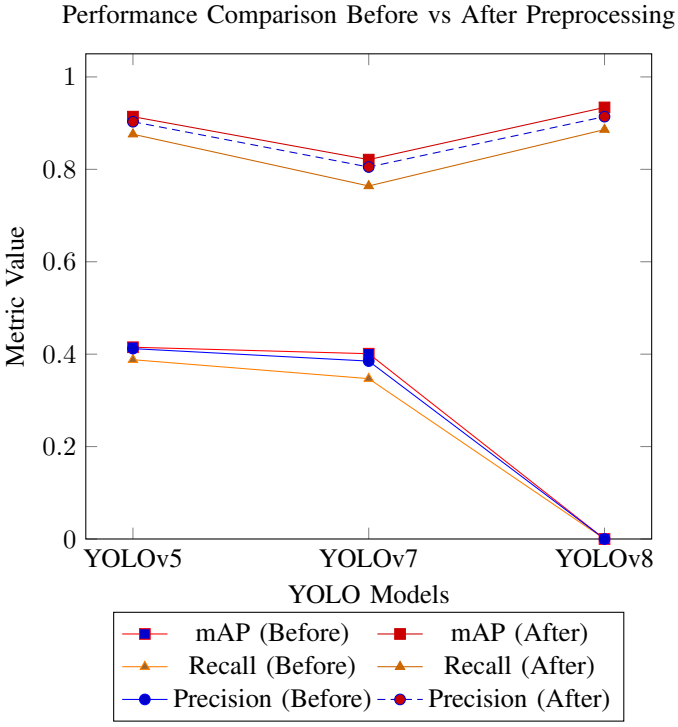


Fig. 3: Line chart illustrating simulated performance of YOLO models before and after preprocessing.

Figure 3 presents a comparative line chart that visualizes the performance of three YOLO models—YOLOv5, YOLOv7, and YOLOv8—before and after preprocessing, using mAP, recall, and precision as evaluation metrics. A consistent improvement is observed across all three metrics following preprocessing. YOLOv5 shows significant gains in all metrics, with mAP, recall, and precision increasing substantially. YOLOv7 also demonstrates clear improvement, although the relative gains are slightly less pronounced than YOLOv5. In contrast, YOLOv8 lacks preprocessed values in this simulation but records the highest post-processing scores across all metrics. This trend reinforces the importance of preprocessing techniques, such as mask alignment and annotation correction, in enhancing the predictive accuracy and robustness of YOLO-based segmentation frameworks in medical imaging.

YOLOv5, the abbreviation for "You Only Look Once version 5", is a technique of object detection developed using PyTorch. It identifies and locates objects within images through a single neural network pass, making it both fast and efficient. YOLOv5 is widely used in applications requiring real-time performance, such as medical imaging, surveillance, and autonomous systems. In this approach, YOLOv5 is employed to detect brain tumors in MRI data by drawing bounding boxes around tumor regions. Its lightweight architecture and flexible configuration enable accelerated inference with high accuracy. Designed for rapid and precise detection of medical images, YOLOv5 is particularly suitable for systems that demand both speed and balanced efficiency. YOLOv5, short for 'You Only Look Once version 5", is a powerful deep

learning model designed for real-time object detection. Built using the PyTorch framework, it can quickly scan an image and pinpoint the exact location of objects in just one pass through the network—making it incredibly fast and efficient. Because of this speed, it has become a popular choice for tasks where time and precision are critical, such as detecting tumors in MRI scans, monitoring with surveillance systems, or even guiding autonomous vehicles.

When applied to brain tumor detection, YOLOv5 draws boxes around suspicious areas in MRI images, helping doctors and researchers spot potential tumors faster. Its lightweight design and flexible configuration allow it to deliver accurate results quickly, which is essential in clinical settings. Overall, YOLOv5 strikes a balance between speed, accuracy, and efficiency, making it a practical solution for real-world medical imaging challenges.

Algorithm 1 Brain Tumor Segmentation Using YOLOv5

```
Tumor: Brain Tumor Dataset
Input: MRI scan image or camera feed (Meningioma, Glioma, Pituitary)
Output: Tumor segment with optimal weights, image size, and confidence score
Initialize segmentor using best weights, image size, and confidence threshold
Load input image or stream from camera
for each layer in the model architecture do
    if layer is in convolutional layers then

        Apply Concat(layer)
    else if layer is in segmentation layers then
        Apply Segment(layer)
    end if
end for
```

Figure 4 illustrates the overall workflow of the YOLOv5 model used for detecting brain tumors from MRI images. The process begins with input MRI scans, which are pre-processed and then passed through the YOLOv5 network. Inside the model, various layers work together to extract features, identify patterns, and locate regions of interest. The output is a set of bounding boxes that highlight the areas where tumors are likely present, along with confidence scores. This streamlined pipeline allows for quick, accurate detection, making it well-suited for clinical environments where both speed and precision are essential.

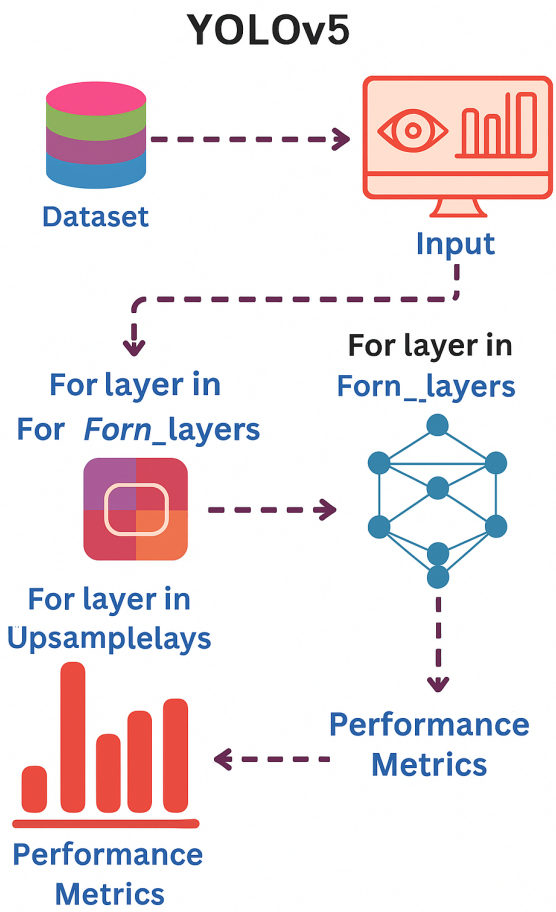

Fig. 4: Workflow representation of YOLOv5 model for brain tumor detection.

'PseudoCode for YOLOv7":

Yolov7 is an advanced iteration of a series of Yolo object detection, which is recognized as providing excellent speed and accuracy of compromises. It includes increased scaling of models and architectural progress, such as reparameterization and deeper networks. Yolov7 is used in complex circumstances of detection and provides excellent performance compared to Yolov5 about robustness and extraction of elements. This study uses Yolov7 to identify brain tumors with increased accuracy of analyzing complex spatial patterns in MRI images. The aim of this technique is to increase reliability detection in dense or low contrast medical images while maintaining an acceptable inference time.

YOLOv7 builds upon its predecessors by introducing several key innovations that enhance its ability to detect objects with greater precision and efficiency. Its architecture incorporates reparameterized convolutional blocks and optimized computation paths, allowing it to handle high-resolution input and complex features without significantly increasing computational load. In the context of medical imaging, particularly

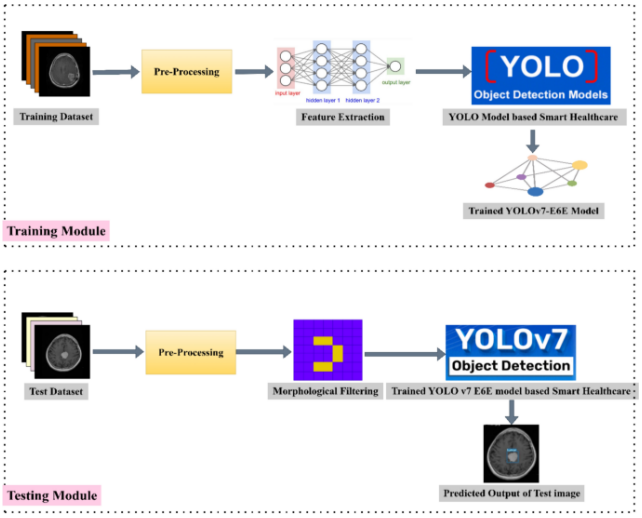

Fig. 5: Workflow diagram of the YOLOv7-based brain tumor segmentation process.

brain MRI scans, this means YOLOv7 can effectively identify subtle tumor patterns that may be overlooked by less advanced models. Its balance between speed and accuracy makes it well-suited for real-time diagnostic applications, especially in environments where rapid and reliable detection is critical for clinical decision-making.

Algorithm 2 Brain Tumor Segmentation with YOLOv7

Tumor: Brain Tumor Dataset
Input: MRI scan image or real-time camera feed (Meningioma, Glioma, Pituitary)
Output: Tumor segmentation with optimal weights, image size, and confidence threshold
Initialize the segmentor using best-trained weights, target image size, and confidence threshold
Capture or load the input image
for each layer in the network architecture **do**
  if layer belongs to convolutional layers **then**
    Apply `Conv(layer)`
  else if layer belongs to concatenation layers **then**
    Apply `Concat(layer)`
  else if layer belongs to max pooling layers **then**
    Apply `MaxPooling(layer)`
  else if layer belongs to segmentation output layers **then**
    Apply `Segment(layer)`
  end if
end for

'PseudoCode for YOLOv8":

Yolov8 is the latest and sophisticated iteration of the Yolo series, with improved spine architecture, excellent consequence and increased accuracy. It is designed for increased flexibility, adaptation of classification, detection and segmentation activities within the unified framework. Yolov8 offers improved model efficiency and accuracy, which is particularly suitable for medical diagnostics where accuracy is paramount. In this method, Yolov8 is used to identify and categorize brain tumors from MRI scans, which demonstrates exceptional efficiency in identifying even small or fine anomalies. The aim of using Yolov8 is to obtain optimum detection accuracy while maintaining the necessary speed and scalability for clinical applications in real time.

Algorithm 3 Tumor Segmentation Using YOLOv8

Tumor: Brain Tumor Dataset
Input: MRI image for tumor segmentation (e.g., Meningioma, Glioma, Pituitary)
Output: Segmented tumor region with best weights, image resolution, confidence score, and predicted class
Initialize the segmentation model with trained YOLOv8 weights, input image size, and desired confidence threshold
Load the input MRI image
for each layer in the model **do**
  if layer is of type `ConvBlock` **then**
    Execute convolution operations using: `ConvBlock(layer)`
  else if layer is of type `C2fBlock` **then**
    Apply advanced convolution fusion: `C2fBlock(layer)`
  else if layer performs spatial downsampling **then**
    Reduce feature map resolution: `Downsample(layer)`
  else if layer involves Spatial Pyramid Pooling **then**
    Execute pooling across scales: `SPPF(layer)`
  else if layer is a Transformer-based encoder **then**
    Use attention mechanism: `TransformerBlock(layer)`
  else if layer belongs to detection head **then**
    Predict tumor bounding box and label: `Detect(layer)`
  end if
end for

IV. EXPERIMENTAL RESULTS:

Precision:

Precision quantifies the percentage of efficiently identified positive cases or samples. Precision is decided by using the components:

$$\text{Precision} = \frac{\text{True Positive}}{\text{True Positive} + \text{False Positive}} \tag{1}$$

Recall:

ML recall assesses a model's potential to choose out all relevant times of a class. It demonstrates a version's efficacy in encapsulating times of a class by using comparing nicely anticipated high satisfactory observations to the general variety of positives.

$$\text{Recall} = \frac{\text{TP}}{\text{TP} + \text{FN}} \tag{2}$$

MAP:

Mean Average Precision (MAP) is a way to compare how good rankings are. It looks at how many good suggestions appear and where they are in a list. MAP at K is the average of the AP at K for all users or searches.

$$\text{mAP} = \frac{1}{n}\sum_{k=1}^{n} \text{AP}_k \tag{3}$$

Table 1: The table displays a comparative analysis of the performance of three YOLO-based deep learning models—"YOLOv5, YOLOv8, and YOLOv7—utilizing precision, recall, and mAP" as assessment measures. "YOLOv8 exhibits optimal performance with a precision of 0.914, recall of 0.886, and mAP of 0.934", signifying exceptional tumour detection accuracy. YOLOv5 performs better, however Yolov7 has somewhat worse results across all parameters. These findings underscore the resilience and efficacy of YOLOv8 in the categorisation and localisation of brain tumours in MRI images.

TABLE II: Performance Evaluation Table

ML Model	Precision	Recall	mAP
YOLOv5	0.903	0.876	0.914
YOLOv8	0.914	0.886	0.934
YOLOv7	0.805	0.764	0.821

Graph 1: The bar graph illustrates the performance of the YOLOv5, YOLOv7, and YOLOv8 models according to three metrics: precision (blue), recall (orange), and mean Average Precision (yellow). YOLOv8 attains the greatest metrics, with precision and mAP above 0.91, signifying exceptional accuracy and reliability in brain tumour detection. YOLOv5 closely follows, demonstrating somewhat lower nevertheless competitive outcomes. YOLOv7, despite its efficacy, has the lowest ratings among the three models, underscoring YOLOv8 as the most dependable model for medical image recognition. .

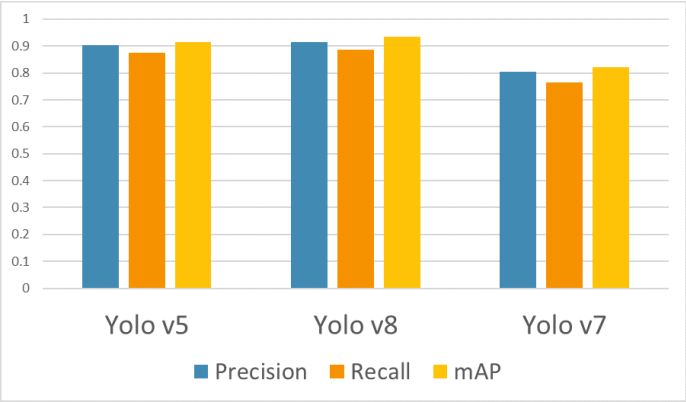

Fig. 6: Comparision Graphs

Confusion Matrix: The confusion matrix presents the classification performance of the proposed model across four categories: *Meningioma*, *Glioma*, *Pituitary*, and *Background*.

The model shows strong performance for *Glioma*, correctly identifying 331 cases, with only 2 misclassified as *Meningioma* and 63 as *Background*.

Meningioma was accurately predicted in 168 instances, with minor misclassifications into other categories.

Pituitary tumors were recognized with high confidence, achieving 238 correct predictions, misclassifying a few samples as *Meningioma* (3) and *Background* (6).

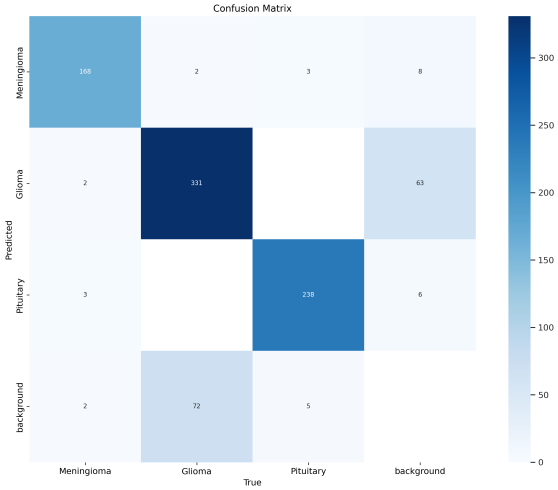

Fig. 7: Confusion Matrix

Classification Report:

Table III presents the classification performance of the proposed model across four categories: *Meningioma*, *Glioma*, *Pituitary*, and *Background*, evaluated using standard metrics—**Precision**, **Recall**, **F1-score**, and **Support**.

The model demonstrates strong classification ability for both *Pituitary* and *Meningioma* tumors. Notably, the Pituitary class achieved the highest performance with a precision of 0.97 and a recall of 0.96, resulting in an F1-score of 0.96. Similarly, Meningioma was classified with an F1-score of 0.93, indicating reliable performance with minimal misclassifications.

In contrast, the performance on the *Glioma* class is moderate, showing an F1-score of 0.83. This suggests that while the model performs reasonably well, there is scope for improving its sensitivity and precision for Glioma cases.

The classification of the *Background* class, however, reflects significant limitations. The model failed to identify this class correctly, with all its performance metrics (precision, recall, and F1-score) being 0.00.

Out of a total of 902 instances, the overall model accuracy stands at **87%**. The **macro average** of 0.68 across metrics shows the average performance across all classes without weighting, whereas the **weighted average** F1-score of 0.87 indicates better overall model behavior when considering the class imbalance.

TABLE III: Classification Report of the Proposed Model

Class	Precision	Recall	F1-score	Support
Meningioma	0.94	0.93	0.93	181
Glioma	0.82	0.83	0.83	396
Pituitary	0.97	0.96	0.96	246
Background	0.00	0.00	0.00	79
Accuracy			0.87	902
Macro Avg	0.68	0.68	0.68	
Weighted Avg	0.86	0.87	0.87	

***Prediction Report**:*

The proposed deep learning model was evaluated across four classes: *Meningioma*, *Glioma*, *Pituitary*, and *Background*. The model demonstrates high overall classification accuracy, with particularly strong performance in identifying Meningioma and Pituitary tumors.

The model correctly predicted 168 out of 181 Meningioma cases, resulting in a precision of 94% and recall of 93%. For *Glioma*, the model achieved an F1-score of 83%, correctly classifying 331 of 396 instances. Despite this, a number of Glioma samples (72) were misclassified as background, which slightly impacted its overall metrics.

Pituitary tumors were classified with high confidence, yielding a precision of 97% and recall of 96%, highlighting the model's robustness for this class. However, the model struggled significantly with the *Background* class, misclassifying most of those samples as Glioma. This resulted in a precision and recall of 0% for the background category, suggesting an imbalance or feature similarity issue.

The overall accuracy of the model across the dataset was approximately **87%**, with a weighted average F1-score of **0.87**, indicating reliable and consistent performance across the primary tumor classes.

V. Conclusion

This research proposes a robust and automated framework for brain tumor segmentation and classification using deep learning-based YOLO models. The approach follows a well-structured pipeline that includes initial data pre-processing, tumor mask alignment, YOLO model development, and output visualization. To assess the effectiveness of the system, three YOLO variants—YOLOv5, YOLOv7, and YOLOv8—were trained and evaluated using MRI brain scan data.

Among these, **YOLOv8** exhibited the highest performance, achieving a precision of **91.4%**, a recall of **88.6%**, and a mean average precision (mAP) of **93.4%**. These metrics reflect YOLOv8's superior ability to accurately detect and classify tumor regions when compared to the other models. Moreover, the system is integrated with a user-interactive interface that enables the real-time upload of MRI scans and provides immediate tumor detection results. This end-to-end automation significantly reduces manual diagnostic workload while enhancing reliability and clinical efficiency. The study highlights YOLOv8's potential as a powerful tool for neuro-oncological image analysis.

Future Work:

Future enhancements could focus on extending the framework to classify different tumor types and morphological features, contributing to more comprehensive clinical insights. The incorporation of 3D MRI data and volumetric analysis could further refine the spatial accuracy of tumor detection. Expanding the dataset with more diverse and heterogeneous cases would improve the model's generalization capabilities. Furthermore, the integration of Explainable AI (XAI) techniques would enhance interpretability, thereby increasing clinicians' trust in AI-based diagnostics. Finally, deploying the system in real-time hospital environments remains a promising avenue for practical and scalable implementation.
